

Tmarus rubromaculatus a crab spider

ORDER:ARANEAE INFRAORDER:Araneomorphae
FAMILY:Thomisidae

FLD_GUIDE_DESCRIPTIONS: "The prosoma is gray brown. There may be faint radial lines from the fovea. The eyes are set up on tubercles. The clypeus projects forward and, with the forward-oriented chelicerae, gives this genus a distinctive look. The opisthosoma is gray brown to golden brown. A large posteriorly pointing tubercle is on the end. The legs are tan to gray brown and spotted. The markings tend to be larger than those seen in *Tmarus angulatus*. Otherwise, these species look very similar." (Rose, 2022)

ONLINE_PHOTOS: None on BugGuide or iNaturalist. At this writing, there is one at <https://www.pbbase.com/dydmnd/image/160563910>

DISTRIBUTION_COMMENTS: Found in SE US, north to CT, West to TX, and extending north into the western provinces of Canada.

HABITAT: SC; near lake shore
