

*Pococera unidentified species* No common name

FAMILY: Pyralidae SUBFAMILY: Epipaschiinae TRIBE: [Epipaschiini]

TAXONOMIC COMMENTS: The genus *Pococera* contains a taxonomically challenging group of species with many forms that are difficult to distinguish based on external morphology, coloration, and patterning. Rearing and knowledge of the host species can be helpful in a few instances, and some species can be identified based on external characteristics. However, we find many specimens from North Carolina that are challenging to assign to species with high confidence.

The genitalia of species that have been examined from North Carolina are virtually identical and offer little help in sorting out species (see Structural Photos below). DNA barcoding also offers little help since many of the established names show up in multiple BINs that likely reflect large numbers of misidentified specimens. Unfortunately, no one has any idea which of these specimens are accurately identified. A comprehensive study of North American members of the genus is clearly needed that will hopefully better delineate species boundaries and resolve some of the problems that hamper the accurate identification of specimens from within the state and elsewhere. At present, our assignment of specimens to certain species is best treated as provisional.

Twenty-six species are currently listed for North America north of Mexico (Pohl and Nanz, 2023). Until a systematic revision is done for this genus -- clarifying the differences between the species and providing more guidance about how to identify them -- we lack standards about how to recognize even the traditionally named species and prefer to treat them in many cases only at the generic level.
