TECHNICAL DESCRIPTION, ADULTS:

TECHNICAL DESCRIPTION, IMMATURE STAGES:

ID COMMENTS: A small member of this complex; a winglength measurement is helpful in its identification. The ground color of the forewing is light reddish mixed with darker reddish brown (Forbes, 1954). Schmidt (MPG, accessed 07-21) describes <i>Bellura densa</i> as having a darker purplish tint overall. The basal area is not paler than the lighter portions of the outer wing and often has a pinkish overshading. The orbicular and reniform spots are orange; the orbicular is larger than in <i>obliqua</i> and the reniform is thicker. According to Schmidt (MPG, accessed 07-21), the angle formed by the reniform and the costa is closer to 90 degrees in <i>densa</i> and more oblique in <i>obliqua</i> . The hindwing may have a reddish tint in this species rather than the fuscous found in <i>obliqua</i>

DISTRIBUTION: Our records are all from the Coastal Plain and eastern Piedmont.

FLIGHT COMMENT: Please refer to the flight charts.

HABITAT: Our records come from a variety of wetland habitats including peatlands, bottomlands, marshes, and savannas.

FOOD: Pickerelweed (<i>Pontederia cordata</i>) is the only known native host, but the larvae will also feed on Common Waterhyacinth (<i>Oshuna crassipes</i>), particularly when Pickerelweed is scarce (Center et al., 2002; Wagner et al., 2011). We do not have any feeding records in North Carolina.

**OBSERVATION METHODS:** 

NATURAL HERITAGE PROGRAM RANKS: G5 SNR [S3S4]

STATE PROTECTION: Has no legal protection, although permits are required to collect it on state parks and other public lands.
